January 2012
About this Manual

This section explains summary, chapter overview, abbreviations, and provides useful information.

The contents in this section are as follows:
- Purpose
- Intended Audience
- Chapter Overview
- Typographical Conventions
- Reference Materials
- Abbreviations
- Export Regulations
- Trademarks
- Requests
- Copyright

Purpose

This user guide describes the architecture and features of the Interstage Business Process Manager Analytics (BPMA).

Intended Audience

This manual is intended for System Administrators. It is assumed that the end user has a working knowledge of the following topics:
- Operating system administration
- Application server administration
- Database administration

Chapter Overview

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Overview of Analysis</td>
<td>Basic concepts of Interstage BPM Analytics.</td>
</tr>
<tr>
<td>2</td>
<td>What Analytics Does</td>
<td>Descriptions of architecture and features.</td>
</tr>
<tr>
<td>3</td>
<td>Setting up and Configuring Analytics</td>
<td>An overview of the set-up sequence and configuration process.</td>
</tr>
<tr>
<td>4</td>
<td>Overview of BAM functionalities and Some Examples</td>
<td>Provides contents of getting started with BAM functionalities.</td>
</tr>
</tbody>
</table>

Typographical Conventions

The following conventions are used throughout this manual.

<table>
<thead>
<tr>
<th>Example</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command</td>
<td>User input that must be typed is identified by the Courier font</td>
</tr>
</tbody>
</table>
| screen text| - GUI options to be selected by the end user are bold  
<p>|            | - GUI options that are emphasized are bold      |
| Reference  | Reference material or related documentation is specified in italics |</p>
<table>
<thead>
<tr>
<th>Example</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Command parameters are identified by the Courier font</td>
</tr>
</tbody>
</table>

**Reference Materials**

The following related documentation is also available.

**Release Notes**

Contains an overview of the Analytics software and late-breaking information that could not be included in the manuals.

**Installation Guide**

Explains how to install Analytics.

**Dashboard / Output Guide**

Explains how to use the Analytics Dashboard.

**Administration Guide**

Covers administration tools and tips, message references, and troubleshooting.

**Analytics Studio Guide**

Explains how to use the Analytics Studio to configure parameters that enforce Analytics features.

**Management Console Guide**

Explains how to use the Management Console and Management Commands to configure key parameters, such as how to start/stop the Analytics software service or how to display the software status.

**Process Discovery Guide**

Explains how to use Process Discovery that generates process diagrams using historical data.

**Abbreviations**

The following abbreviations are used throughout this document.

<table>
<thead>
<tr>
<th>Name</th>
<th>Abbreviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft(R) Windows Server(TM) 2003 R2, Enterprise Edition</td>
<td>Windows Server</td>

5.1 As-Is Analysis with Process Discovery .................................................. 35
5.1.1 Comparison with Predicted Flows ...................................................... 35
5.1.2 Detecting Exceptional Routes ............................................................ 35
Chapter 1 Overview of Analytics

The Interstage Business Process Manager Analytics (BPMA) software provides functionality for Business Activity Monitoring (BAM), including data collection and analysis.

The process visualization features of Process Discovery depict the current state and improvements in your business. Use it with the Interstage Business Process Manager (BPM) for effective business process visualization and enhance your business performance.

1.1 Business Activity Monitoring - BAM

A comprehensive Business Activity Monitoring (BAM) suite enables all your business processes to be monitored using one centralized application. The BAM suite is designed to complement and effortlessly integrate with the Interstage BPM, and also, access and utilize other data sources in a wider business environment.

Analytics facilitates superior data collection, analysis, and display functionality associated with the modern BAM architecture. All this can be scheduled to occur real-time or periodically.

Moreover, the results of an analysis can be viewed graphically using the Analytics Dashboard or other actions could be initiated, such as e-mails to responsible parties or invoke another application. Data could also be exported to another analysis system, for instance, as a .csv log file.

1.2 Process Visualization (Process Discovery)

Process Discovery enables you to assess the level to which an IT system suits a particular business. It allows you to analyze the data accumulated in an IT system to yield critical information about how the IT system is used real time.

The data accumulated in the database tables of an IT system is fed into Process Discovery and a chart showing the business processes is generated as the output. These charts can be in many different styles and the analysis can be from different viewpoints, making it easier to identify issues and problems of an IT system or business process.

The data fed into Process Discovery is in the text, Comma-Separated Value (CSV), format. It is a simple matter of converting the data, stored in a database or worksheets, into a CSV, and then, feeding it into Process Discovery. So, if you already have the CSV data, you can easily analyze your business processes using Process Discovery.
Chapter 2 What Analytics Does

The Interstage Business Process Manager Analytics (BPMA) is capable of the following three types of analysis:

- Analysis of real-time information/data from existing systems such as applications, databases, and ERP systems
- Analysis of the performance of business processes as an Interstage BPM extension
- “As-Is” analysis of business processes based on results

2.1 Components of Analytics

The following graphic demonstrates the role of Analytics in a business environment that uses the Interstage Business Process Manager (BPM) as well as other application/ERP components.

Analytics comprises five main modules:

**Sensors**

Enable connection with other business systems and gather business data, referred to as events, from those systems; events are generated from text or .csv files, databases, and Interstage BPM systems.

**Analytics Engine**

Captures all data, ensures it is in the common format, and then, analyzes it according to the business rules set up in the Analytics Studio.

**Front Service**

Represents the event information in a dashboard-style display; data can be either presented through e-mail notifications or actions, such as calling another application or event, or simply, exported as raw data to another application.

**Process Discovery — Process Generator**

Generates business processes from CSV-format business logs.

**Process Discovery — Process Analyzer**

Analyzes the business processes generated by the Process Generator and produces visualizations of the processes; if the Interstage BPM business process data is collected as Analytics events, this data is shown as processes.
2.2 How Analytics Works

2.2.1 Event Collection

The event collection function collects business data from the entire business and stores it as events in the Events database. The scope of Analytics collection capabilities extends beyond the processes defined in the Interstage BPM and can include data and information from other data sources that are within the business.

Events to be collected and the configuration of their sensors is defined and configured in the Analytics Studio.

Analytics can monitor the following systems.

**Workflow of Interstage BPM processes**

Analytics can collect, as events, a variety of historical information such as process start, activity start and completion, user-defined information, as well as performance information on how well the processes within the BPM system are running.

**RDB**

At regular intervals, the Analytics RDB monitoring function can be set to collect data from business databases and store them in the Events database in a common format.

**Text files**

Data that has been saved in text files during business system operations can also be collected as events. Analytics can collect CSV and fixed-recorded file, which is usually used by legacy systems.

Text file monitoring can be used to periodically browse within files and collect, as events, the parts that have been added.

Additionally, collection conditions can be set so that only specific data that matches those conditions is collected. For example, an event "Monitoring of travel-expense applications that exceed a total of $100 at 30 minute intervals" can be implemented using Analytics.

Schedules and rules for event collection can also be set.

---

**Note**

There are two types of text file sensors—sensors that operate as web applications and sensors that operate as Microsoft Windows Services (Windows Service Edition Text File Sensor). The Windows Service Edition Text File Sensor can be used to collect monitoring data from client systems.

---

**Setting event collection schedules**

Users can set schedule for event collection, such as, specific time intervals, every week, or at the end of each month. These settings are configured using the Analytics Studio.

2.2.2 Event Processing

The ability to calculate statistical data and run functions on events to produce meaningful, custom-made analysis is the most important Analytics feature.

These calculations are done by the Analytics Engine that uses data stored in the Events database.

The event processing function performs statistical calculation and alert assessment on the collected events.

**Statistical calculation**

Using the Analytics Studio, statistical settings or rules can be defined for events. For example, the sum or average of events can be calculated. Statistical results are managed as statistical events in the Events database.
Alert assessment

The Analytics Engine assesses the collected events by setting conditions that use threshold values. If these thresholds are exceeded, an alert is triggered. Alerts can, in turn, become events of statistical results, saved in the Events database.

Examples of alerts include:
- Checking events by parameter values
  Example: When monthly sales are less than $5,000,000
- Checking the progress of a process
  Example: When a process step is not completed three days before the next step's completion due date

2.2.3 Event Visualization

When the Analytics Server starts working, it collects events from variety of sources. These are stored in the Events database using a common format. There the data is processed by the Analytics Engine and the results are also stored in the Events database, available for presentation.

Presentation can occur in a number of ways.

While the most obvious use of the results is to present the information in a dashboard so that it is visible and useful to managers and other analysts, the results can also be used to trigger a new event, for example, to send an e-mail or invoke another application.

The analysis data can also be output as a file to be used in another analysis system.

Dashboard

The status of business activities can be displayed using graphs or tables, while the status of alerts can be displayed real time. This enables rapid and effective response to events (for example, errors) that can occur in a business process.

The Analytics Dashboard is defined as a profile in the Analytics Studio. Components such as charts, alerts, and statistics can be included in each profile.

Alerts and escalation

In addition to presenting data and results on the Analytics Dashboard, various other operations are possible with the Analytics Front Service.

The alerts, created using the Analytics Studio Alert wizard, are used to create alert tabs in the Analytics Dashboard (as described in the previous section), and then, the following operations are possible.

Use alerts as trigger mechanisms to launch other events or send messages.

Alerts / escalation

The content of an alert can be sent to a user by e-mail.

Set this in the Analytics Studio.

Calling external applications

Escalation can also involve a call to external services or applications. The launch can be set as the response to an event.

Set this in the Analytics Studio.

Linking data with external tools

Data can also be exported to an environment outside Analytics.

The monitoring results in the Events database can be output to CSV files, so that this data can be linked to other systems or analyzed using tools, such as Microsoft Excel. Use the management command to output data in the CSV format.

Reports

Use the Analytics Studio Reports tool to generate reports.

Reports have their own schedule and profile.
Reports can also include one or more KPI charts or alerts list.
When you define reports in the Analytics Studio, set the schedule for creating reports and specify the Profile layouts to be used for generating them.

2.2.4 Process Generation using Process Generator

Processes are generated by the Process Discovery - Process Generator using the data accumulated in a business database. Key features of process generation include:

- Profiling
  Analyzes the peculiarities of the data and extracts candidates that can be used as time information and event types
- Correlation Candidate Selection
  Allows you to select the correct event types and set the correlations between events
- Process Data Generation
  Takes the information determined above and creates processes from the CSV data, storing the results in the Process Discovery database

2.2.5 Process Analysis using Process Analyzer

The Process Discovery - Process Analyzer analyzes and displays the business process data generated by the Process Generator or Interstage BPM. Key features of process analysis include:

- Process Analysis
  Allows you to filter process data, display processes, and detect bottlenecks
- Route Analysis
  Analyzes routes or order of events in processes; uses the principles that if the order of occurrence of events is the same in processes, the same route is followed
- Exceptional Route Analysis
  Analyzes processes that do not have the same route or order of events as majority of processes in a business environment
- Parallel Analysis (only when displaying Interstage BPM)
  Allows you to view the extent to which simultaneous events overlap
Chapter 3 Setting Up and Configuring Analytics

This chapter provides an overview of how to setup and configure the Interstage Business Process Manager Analytics (BPMA).

Setting Up BAM

The following illustration shows the setup procedure.

Setting Up Process Discovery

The following illustration shows the setup procedure.
Chapter 4 Overview of BAM functionalities and Some Examples

This chapter gives an overview of BAM functionalities and some examples.

4.1 Overview of Event Collection

4.1.1 Data Types and Monitoring Methods

Configure event collection to match business requirements by combining the settings for data types and monitoring methods.

The following table describes the two data types.

<table>
<thead>
<tr>
<th>Data types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Master Data Management</td>
<td>Covers data used for updating, such as inventories and summaries.</td>
</tr>
<tr>
<td>Transaction Data Management</td>
<td>Covers data that is added, such as sales and transaction records.</td>
</tr>
</tbody>
</table>

The following three monitoring methods are available:

- Add difference records
- Easy mirroring
- Full history

The behavior of event collection depends on the combination of the data and monitoring methods used, as described in the following table.

| Data types                | Monitoring method      | Event collection behavior                                                                 |
|---------------------------|------------------------|============================================================================================|
| Master Data Management    | Add difference records | Only records that have been added to a business database are added to Analytics data as new records. |
| Master Data Management    | Easy mirroring         | Records added to a business database are added to Analytics data as new records. If records are updated on the business database, they are similarly updated in the Analytics data. |
| Master Data Management    | Full history           | All data is gathered with every collection and stored in Analytics. |
| Transaction Data Management| Add difference records | * Behavior is the same as the Master Data Management/Add difference records combination. |
| Transaction Data Management| Easy mirroring         | * Behavior is the same as the Master Data Management/Easy mirroring combination. |
| Transaction Data Management| Full history           | Records added to a business database and data updated on a business database are both added to Analytics data as new records. |

4.1.2 Master Data Management with Add Difference Records

When event collection occurs once a day, and where the following changes are apparent in the data between one day and the next, only data that is added is reflected as updates in the Events database. The behavior will be the same for Transaction Data Management with Add difference records.
4.1.3 Master Data Management with Easy Mirroring

When event collection occurs once a day, and where the following changes are apparent in the data between one day and the next, data that is added is reflected as a new event in the Events database, and updated data is reflected in the Events database as updates. The behavior will be the same for Transaction Data Management with Easy mirroring.
4.1.4 Master Data Management with Full History Monitoring

When event collection occurs once a day and when the following changes are apparent in the data between one day and the next, all monitored data is collected and stored in the Events database.
4.1.5 Transaction Data with Full History Monitoring

When event collection occurs once a day, and where the following changes are apparent in the data between one day and the next, data that is updated and data that is added is stored in the Events database as new events.
4.2 Event Collection Example

4.2.1 RDB Sensor (To Detect Added Records)

In the following example, an RDB sensor collects business data from a business database and stores it in the Events database as a general event. In this example, the business table contains a time column that records the time when events occur; this time can be used to distinguish which records should be collected as events. The RDB sensor only collects new records from the business database and adds them to the Events database.
Specify which table and column to collect data from in a collection task. The example shows that data is to be collected from the SALES_ITEM table, starting at column_A and ending at column_Y. The column used to distinguish events is set as column_A (the column used to record the time when events occurred). A user-defined constant has also been added (the "Country" column with the value "Japan").

Next, use an event to specify the item names and data types for the items that store the collected data. The example shows items that store data from "column_B" have been labeled "Sales item", and the items that store data from "column_C" have been labeled "Number sold".

Finally, use a collection schedule to specify the collection timing. In this example, the collection schedule has been set to "every hour". The collection task will be executed every hour, so long as the sensor is running.

### 4.2.2 RDB Sensor (To Detect Updated Records)

In the following example, an RDB sensor collects business data from a business database and stores it in the Events database as a general event. In this example, the business table does not contain a time column that records the time when events occur, so time cannot be used to distinguish which records should be collected as events. All records from the business database are collected and added to the Events database. This information can be used to manage stock level trends, for example.
All three records ("Fruit gift", "Drink gift" and "Flower gift") are collected every hour and added to the Events database. This makes it possible to work out, for example, that the stock levels for "Fruit gift" have dropped from 2500 at eight o’clock to 2100 at nine o’clock.

4.2.3 RDB Sensor (Merging from Separate Tables)

In the following example, an RDB sensor collects data from two business tables in a business database and stores this data in the Events database as a single general event.
Create a collection task for business table X, and then create an event to store the collected data. Next, create a collection task for business table Y, and then specify how business table Y and the event created with the collection task for business table X correspond. User-defined constants can also be added as identifiers used when the data is merged. In this example, an "Area code" has been added.

### 4.2.4 RDB Sensor (Merging into the Same Event from Separate Tables)

In the following example, data is collected from two tables in a business database by an RDB sensor, merged into one event, and stored in the Events database.
Create collection tasks for both the Production table and the Shipping table, mapping the attributes that represent items sold and dates to the event keys defined in the general event. When events are generated based on the data from two tables, as shown above, the event that arrives first is added as a new event. The event arriving later then uses the event keys to determine the relevant attributes and updates them.

4.2.5 RDB Sensors (Comparing against the Master Table)

In the following example, an RDB sensor collects and merges data from two business tables in a business database and stores this data in the Events database as a single general event.
Example 1: Using join keys (collecting general events 1)

A collection task is created using "column_B" in the Sales slip table and "column_A" in the Item master table as join keys. This makes it possible to collect business data from multiple tables and integrate this data as a single event. In this example, "ITEM0001" in "column_B" is associated with the "Fruit gift" sales item in the Item master table and stored in the Events database. Doing so makes monitoring windows and CSV file output easier to understand.

Example 2: Using a FROM clause (collecting general events 2)

There is no join key in example 2, so items are associated with the Item master table by using an "INNER JOIN" in the FROM clause. The condition in "column_B" of the Sales slip table should be the same as "column_A" of the Item master table, which is defined using the table name specification for the collection task.

The results are the same as example 1.
4.2.6 Text File Sensors (Fixed File Names)

In the following example, text file sensors collect data from a file with a fixed name and store this data in the Events database as general events. This can be used with Business Processes where logs are always output with the same file names.

In the collection task, specify the file and location in the file of the data to be collected. In this example, the first, second, third and fourth data elements in the file "Log.csv" have been specified.

Next, use an event to specify the item names and data types for the items that store the collected data. In this example the labels of the four items are "Person in charge", "Amount", "Branch name", and "Approver".

Finally, use a collection schedule to specify the collection timing. In this example, the collection schedule has been set to "every 5 seconds". The collection task will be executed every 5 seconds so long as the sensor is running.

It is also possible to specify that all data within the file is to be collected with each collection.

4.2.7 Text File Sensors (Files with Rotating Names)

In the following example, text file sensors collect data from files whose names contain a particular string, and store this data in the Events database as general events. This can be used with Business Processes where new log files are created once the current log file reaches a certain size and where these log file names contain a particular string.
In the collection task, specify the file and location in the file of the data to be collected. In this example, the first, second, third and fourth data elements in a file that includes the string "Log" have been specified.

Next, use an event to specify the item names and data types for the items that store the collected data. In this example the labels of the four items are "Person in charge", "Amount", "Branch name", and "Approver".

Finally, use a collection schedule to specify the collection timing. In this example, the collection schedule has been set to "every 5 seconds". The collection task will be executed every 5 seconds so long as the sensor is running.

**4.2.8 Text File Sensors (Transfer File Group)**

In the following example, text file sensors collect data from all of the files in a particular directory and store this data in the Events database as general events. This can be used with Business Processes where log information is transferred or copied to a particular directory as a file, once it has been written completely.
In the collection task, specify the file and location in the file of the data to be collected. In this example, the first, second, third and fourth data elements in all the files in the folder "C:\Directory" have been specified.

Next, use an event to specify the item names and data types for the items that store the collected data. In this example the labels of the four items are "Person in charge", "Amount", "Branch name", and "Approver".

Finally, use a collection schedule to specify the collection timing. In this example, the collection schedule has been set to "every 5 seconds". The collection task will be executed every 5 seconds so long as the sensor is running.

4.3 Event Processing

4.3.1 Event Calculation (Calculation Operations)

In the following example, new calculation events are output by performing calculations on the general events stored in the Events database.
Example 1: Calculating sales totals grouped by area code

Calculations are performed on general events every hour. A group attribute has been specified, and so separate calculations are made for each group of events with the same group attribute (in this case, "area code"). For example, at eight o'clock calculations are made for the general events that have occurred in the last hour (since seven o’clock). Since there are no general events with the area code "KANTO", the "Total sales" for this group is "0". There are two events with the area code "KANSAI" (1000 for the "First tea of the season" event with the "Osaka" sales area code, and 2100 for the "Strawberries" event with the "Kyoto" sales area code) and so the "Total sales" is "3100".

Example 2: Working out average values from sales totals

Calculations are performed on general events every hour. Group attributes have not been specified, and so one statistics event is output for each calculation. For example, at eight o’clock, the "Total sales" and "Sales average" are calculated for the following general events that have occurred in the hour since seven o’clock.

- 1000 for the "First tea of the season" event with the "Osaka" sales area code
- 2100 for the "Strawberries" event with the "Kyoto" sales area code

The "Total sales" is 3100 and the "Sales average" is 1550.
In the following example, new statistics events are output by performing arithmetical operations on the general events stored in the Events database.

<table>
<thead>
<tr>
<th>Event occurrence time</th>
<th>Order ID</th>
<th>Sales price</th>
<th>Cost price</th>
<th>Area code</th>
</tr>
</thead>
<tbody>
<tr>
<td>2006.07.13 01:50:00</td>
<td>XYZ003</td>
<td>2000</td>
<td>800</td>
<td>KANSAI</td>
</tr>
<tr>
<td>2006.07.13 02:20:00</td>
<td>XYZ004</td>
<td>1000</td>
<td>650</td>
<td>KANSAI</td>
</tr>
<tr>
<td>2006.07.13 03:05:00</td>
<td>XYZ2005</td>
<td>4000</td>
<td>900</td>
<td>KANTO</td>
</tr>
<tr>
<td>2006.07.13 0:30:00</td>
<td>XYZ2007</td>
<td>2000</td>
<td>900</td>
<td>KANSAI</td>
</tr>
</tbody>
</table>

**[Configuration of statistical event]**
- Calculation period: 1 hour
- Output item 1: use the same “Order ID”
- Output item 2: calculate “Cost rate” from “Cost price” divided by “Sales price”
- Group attribute: “Order ID”

This example generates the cost price ratio from the sales and cost price information in the sales slip.

### 4.3.3 Evaluating Alerts (Parameter Evaluation)

In the following example, alert messages are output by setting up alert rules for evaluating the parameters of single events.
For example, the alert rule "Sales item name" is equal to "Strawberries" will match events (a) and (c), and the message "An order for strawberries was placed" will be displayed in the Alert View of the Dashboard.

### 4.3.4 Evaluating Alerts (Scheduled Evaluation)

In the following example, alert messages are output by setting up alert rules for evaluating the schedule of single events.

<table>
<thead>
<tr>
<th>Event occurrence time</th>
<th>Sales item</th>
<th>Number sold</th>
<th>Unit price</th>
<th>Sales</th>
<th>~</th>
<th>Sales area</th>
<th>Area code</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Fruit gift</td>
<td>3</td>
<td>500</td>
<td>1800</td>
<td>~</td>
<td>Tokyo</td>
<td>KANTO</td>
</tr>
<tr>
<td>b</td>
<td>Drink gift</td>
<td>5</td>
<td>1500</td>
<td>7500</td>
<td>~</td>
<td>Kyoto</td>
<td>KANSAI</td>
</tr>
<tr>
<td>~</td>
<td>~</td>
<td>~</td>
<td>~</td>
<td>~</td>
<td>~</td>
<td>~</td>
<td>~</td>
</tr>
<tr>
<td>c</td>
<td>Fruit gift</td>
<td>2</td>
<td>500</td>
<td>1200</td>
<td>~</td>
<td>Osaka</td>
<td>KANSAI</td>
</tr>
</tbody>
</table>

**Example of alerting conditions**

- "Sales item" is equal to "Fruit gift".
- "Number sold" is 5 or greater.
- "Number sold" times "unit price" is 1500 or less.
- "Area code" is equal to "KANSAI" and "Number sold" is "5" or greater.
- "Sales item" includes "Fruit gift" and "Sales area" is "Osaka".
- "Number sold" is "10" or greater, or "Sales" is "5000" or more.

<table>
<thead>
<tr>
<th>Matched events</th>
<th>Example of alerting messages</th>
</tr>
</thead>
<tbody>
<tr>
<td>a, c</td>
<td>Fruit gift was ordered.</td>
</tr>
<tr>
<td>b</td>
<td>Order of 5 or greater was placed.</td>
</tr>
<tr>
<td>a</td>
<td>Order of 1500 yen or less was placed.</td>
</tr>
<tr>
<td>c</td>
<td>Order for 5 or more items was placed in KANSAI.</td>
</tr>
<tr>
<td>c</td>
<td>Order related to Fruit gift was placed in Osaka.</td>
</tr>
<tr>
<td>b</td>
<td>Large order was placed.</td>
</tr>
</tbody>
</table>
Events such as D and E can be detected by setting up alert rules as shown above. Alert messages will be displayed in the Alert View of the Dashboard.

### 4.3.5 Evaluating Alerts (Parameter Evaluation for Pair Events)

In the following example, alert messages are output by setting up alert rules for evaluating the parameters of pair events.

#### Example of alerting conditions

| Issue an alert if the date is neither the 20th nor the 21st and "Process detail = Update" and "Target object = Monthly calculations". |
| → |
| Issue an alert if the time is outside the range "8:00 - 10:00" and "Process detail = View" and "Target object = Inventory master". |

<table>
<thead>
<tr>
<th>Matched events</th>
<th>Example of alerting messages</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Error: The Monthly total was updated on a date other than the 20th or the 21st.</td>
</tr>
<tr>
<td>E</td>
<td>Warning: The inventory master was viewed either early in the morning or late at night.</td>
</tr>
</tbody>
</table>

Events such as D and E can be detected by setting up alert rules as shown above. Alert messages will be displayed in the Alert View of the Dashboard.

### General event (Events DB)

<table>
<thead>
<tr>
<th>Event occurrence time</th>
<th>Process detail</th>
<th>Target object</th>
<th>Person in charge</th>
</tr>
</thead>
<tbody>
<tr>
<td>2006.07.13 11:50:00</td>
<td>View</td>
<td>Inventory master</td>
<td>Operator</td>
</tr>
<tr>
<td>2006.07.20 02:00:00</td>
<td>Create</td>
<td>Monthly total</td>
<td>Manager</td>
</tr>
<tr>
<td>2006.07.21 09:15:00</td>
<td>Update</td>
<td>Monthly total</td>
<td>Manager</td>
</tr>
<tr>
<td>2006.07.24 08:46:00</td>
<td>Update</td>
<td>Monthly total</td>
<td>Manager</td>
</tr>
<tr>
<td>2006.07.27 04:25:00</td>
<td>View</td>
<td>Inventory master</td>
<td>Operator</td>
</tr>
</tbody>
</table>

### General event A (Events DB)

<table>
<thead>
<tr>
<th>Event occurrence time</th>
<th>Order ID</th>
<th>Type</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>2006.07.13 00:35</td>
<td>XY2006</td>
<td>Order</td>
<td>300</td>
</tr>
<tr>
<td>2006.07.13 00:35</td>
<td>XY2007</td>
<td>Order</td>
<td>1000</td>
</tr>
<tr>
<td>2006.07.13 00:35</td>
<td>XY2008</td>
<td>Order</td>
<td>3000</td>
</tr>
</tbody>
</table>

### General event B (Events DB)

<table>
<thead>
<tr>
<th>Event occurrence time</th>
<th>Order ID</th>
<th>Type</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>2006.07.15 00:00:00</td>
<td>x(2006)</td>
<td>Ship</td>
<td>300</td>
</tr>
<tr>
<td>2006.07.15 14:00:00</td>
<td>x(2007)</td>
<td>Ship</td>
<td>100</td>
</tr>
<tr>
<td>2006.07.15 11:41:20</td>
<td>x(2006)</td>
<td>Ship</td>
<td>3000</td>
</tr>
</tbody>
</table>

**Configuration of alert rule**
- Rule type: check parameters between pair events (general events)
- Base event: set "type = order" for general event A
- Other event: set "type = shipment" for general event B
- Pair attributes: "Order ID"
- Condition: "quantity" of base event does not equal to "quantity" of other event

**Example of alerting messages**

Error:
The quantity of order does not equal to the quantity of shipment in "Order ID: XY2007".
- Quantity of order: 1000
- Quantity of shipment: 100
The attribute data values of two events can be compared as shown above by setting up "Order ID" as the pairing attribute and "Quantity" of the base event is not equal to "Quantity" of other event" as the determination rule.

4.3.6 Evaluating Alerts (Order Evaluation for Paired events)

In the following example, alert messages are output by setting up an order evaluation alert rule for paired events.

This is an example of a business activity where events are collected in three phases ("Acceptance", "Payment confirmation", and "Product preparation") after orders are placed, and then stored in the Events database. This section explains what happens when alert rules are set up for the "Payment confirmation" and "Product preparation" events of this business activity.
Example 1: Issue a completion report if "Product preparation" occurs within 2 days of "Payment confirmation"

This alert rule is used to confirm that the business activity has been processed normally.

An alert message advising of completion is output if the "Product preparation" event occurs within two days of the "Payment confirmation" event to which it is being compared. Comparisons are made for the same order by specifying "Slip ID" as the group attribute.

Example 2: Issue an alert if "Product preparation" does not occur within 2 days of "Payment confirmation"

This alert rule is used to detect business activities that have been delayed.

An alert message advising of the delay is output if the "Product preparation" event does not occur within two days of the "Payment confirmation" event to which it is being compared. Comparisons are made for the same order by specifying "Slip ID" as the group attribute.

Example 3: Issue an alert if "Product preparation" occurs without "Payment confirmation" having been confirmed

This alert rule is used to detect whether the business activity has been processed incorrectly.

An alert message advising of a business activity error is output if a "Product preparation" event occurs without a preceding "Payment confirmation" event. Comparisons are made for the same order by specifying "Slip ID" as the group attribute.

4.4 Overview of Chart Display

4.4.1 Chart Display (Basic)

In the following example, the events stored in the Events database are displayed as a graph.

![Chart Display Example]

To display this type of graph, select "Bar graph" in the chart display settings, and specify "Total sales" as the data to be graphed, "Event collection time" as the item, "Area code" as the series, and "8:00 - 10:00" as the data collection period. The total sales for the KANTO and KANSAI areas will be displayed as bar graphs for each event, making it possible to see trends in total sales at a glance.
4.4.2 Data Processing

A variety of data is processed to produce the graphs used in chart displays. The following shows these processes.

**Business Event**

<table>
<thead>
<tr>
<th>Event Collection datetime</th>
<th>Region</th>
<th>Product ID</th>
<th>Stock</th>
</tr>
</thead>
<tbody>
<tr>
<td>2011.11.15 06:15:00</td>
<td>Kanto</td>
<td>CODE0004</td>
<td>20</td>
</tr>
<tr>
<td>2011.11.15 07:15:00</td>
<td>Kanto</td>
<td>CODE0002</td>
<td>80</td>
</tr>
<tr>
<td>2011.11.15 08:15:00</td>
<td>Kansai</td>
<td>CODE0003</td>
<td>37</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>2011.11.15 10:15:00</td>
<td>Kyushu</td>
<td>CODE0002</td>
<td>42</td>
</tr>
</tbody>
</table>

[build data]  
- Extract attribute used

[controller calculate Event data]  
- Statistical event 0 plot control  
- Arithmetic operation  
- Calculation of attribute for same category value  
- Calculation by time series

[event data conversion]  
- Compare by time series (optional)  
- Control plot of series (optional)  
- Control plot of category (optional)  
- Sort data by category  
- Sort by series

[generate subgraph]  
- Calculate event data  
- Sort by series

Display chart
1. Retrieve event data from the Events DB

Find the data in the Event DB using period and filter settings. The search results are then retrieved as event data. In the example the period is "XX", so all event data in this range is retrieved.

**Point**

You can avoid drops in performance by setting the period and filter so the number of search records displayed is limited to about 1000.

Note that this is just a guide. Take your system into account when determining this value.

2. Build the dataset

If the event data retrieved is field, series, data property, or an event table, a dataset is created by extracting the data of the specified property. If a sub-graph has been specified, it is extracted at this point.

In the example, the item attribute "Event collection data", the series attribute "Region code", and the data attribute "Sales" are extracted.

3. Adjust and calculate event data

This is where the data is adjusted and calculated. Where field values are duplicated, they are calculated according to the method specified.

If a basic arithmetic operation has been specified in the data properties, that operation is performed. If there is event data with the same date in a field, it is calculated with the statistical operation specified.

4. Convert event data

This is where other optional features can be used to adjust the plotting, etc.

5. Generate sub-graph data

Sub-graphs are processed in the same way as the base graphs.

The above flow shows the processing that data in the Events DB must go through to be displayed as a chart. Charts may be displayed by the above processing, or they may be displayed as the result of statistics events that process the data beforehand. Each method has its merits and demerits. Use the method best suited to your purposes.

Processing data when about to display a chart has the following merits and demerits:

**Merit**

The most up-to-date data is used.

**Demerit**

Display may take a long time or the system may become unstable if the volume of data is great.

Using statistics events to display a chart has the following merits and demerits:

**Merit**

The load caused by display of the chart is reduced by preprocessing the data.

**Demerit**

The data must be processed beforehand so the displayed data will not be the most recent.

**Point**

The frequency of data updating must be taken into account when displaying charts.

When creating a chart of daily sales where the sales data is updated once a day, the data only needs to be processed once a day. By accumulating the data, as it is updated, you can reduce the load on the chart display.

With stock data, that may change minute by minute, the most recent data can be displayed by processing at the time of display. All that needs to be done to reduce the load caused by display is to make the period only as long as necessary.
4.4.3 Chart Display (Advanced)

In the following example, the events stored in the Events database are displayed as a graph, together with the graph from the previous month and threshold values.

<table>
<thead>
<tr>
<th>Event occurrence time</th>
<th>Sales</th>
<th>Sales of previous month</th>
<th>Target figures</th>
<th>Area</th>
</tr>
</thead>
<tbody>
<tr>
<td>~</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2006.07.14 20:00:00</td>
<td>5100</td>
<td>2300</td>
<td>4500</td>
<td>Osaka</td>
</tr>
<tr>
<td>2006.07.14 20:00:00</td>
<td>5700</td>
<td>9100</td>
<td>10000</td>
<td>Tokyo</td>
</tr>
<tr>
<td>2006.07.14 20:00:00</td>
<td>2100</td>
<td>2500</td>
<td>3000</td>
<td>Nagoya</td>
</tr>
<tr>
<td>2006.07.14 20:00:00</td>
<td>5900</td>
<td>2000</td>
<td>2000</td>
<td>Fukuoka</td>
</tr>
</tbody>
</table>

To display this type of graph, select "Bar graph" in the chart display settings, and specify "Total sales" as the data to be graphed, "Area" as the item, "Previous month's figure" as the superimposed data, and "Target line" as the threshold display. This graph makes it possible to compare the current month's figures with the target line and the previous month's figures at a glance.

4.4.4 Chart Drill-Down Display

The following example shows how to drill down through a chart display.
In this example, the “Chart of sales by region” chart has been set as the parent and the “Chart of sales by prefecture” chart has been set as the child. Clicking on the “Kansai” region name in the parent chart causes the display to drill down to the chart for the Kansai region. The general events specified in the chart settings do not have to be the same, different general events can be specified for the parent and child charts.

4.5 Overview of Display Control in the Dashboard

Dashboard Groups are used by the dashboard to connect users and profiles in order to control what is displayed.

Access permissions are granted by first defining Dashboard Groups and then associating users and profiles with these groups.

There is a “guest” group in the system. Users that do not belong to any other group will be allocated to the guest group. A user cannot belong to the guest group and another group at the same time.
4.5.1 Example of Display Control

This example uses production processes and sales processes. Create "Production Processes" and "Sales Processes" Dashboard Groups. By associating Production Department User A with "Production Processes" and Sales Department User B with "Sales Processes", Production Department User A will be able to view only production data. Similarly, Sales Department User B will be able to view only sales data.
4.6 Direct Display

4.6.1 External Filtering

By setting the appropriate request parameters when accessing the KPI view, the filtered data can be displayed in a chart.

This is an example of using HTML tags in a form to filter.

```html
<form method="POST" action="http://hostname/ibpmm/dashboard/Welcome?
   menuType=kpi&viewProfileId=VPR_AAA&chartLayoutId=DLT_BBB">
   <input type="hidden" name="conditionType" value="name" />
   <input type="hidden" name="key0" value="ProductName" />
   <select name="value0" multiple>
      <option value="DVD_media">DVD_media</option>
      <option value="plasmaTV">plasmaTV</option>
      <option value="cooler">cooler</option>
   </select>
</form>
```
Nothing is selected in the example on the left so no filtering is performed on the displayed chart.

"DVD_media" has been selected in the middle example, so only the results for "DVD_media" is shown in the chart.

The example on the right has both "DVD_media" and "plasmaTV" selected, so data for both is displayed in the chart.

Refer to the Interstage Business Process Manager Analytics V12.0 Dashboard / Output Guide for details.

4.7 Overview of Escalation

4.7.1 E-mail Example

Escalation is the process that is performed when an alert occurs. Here we will use e-mail as an example.

E-mails may be created in English and Japanese. A title and body text may be written for the e-mail. Information from the alert may be embedded in these.
4.8 Replacing Event Data

Set up label replacement definitions, a combination of values before and after replacement, to show the replacement values in the dashboard. This is an example of replacing event data for display in the dashboard.

In this example, the product ID is replaced with the product name.
Define label replacement in the **System Settings > UI Management > Label Substitution** tab of the Management Console.

The definitions are set in Studio events for each attribute. The attributes thus set will be replaced for display when shown in the dashboard.
Chapter 5 Some Examples with Process Discovery

This chapter gives some examples with Process Discovery.

5.1 As-Is Analysis with Process Discovery

As-Is analysis with Process Discovery extracts logs from business systems, and then creates processes from the business data with the Process Generator. You can then use the following process analysis tools to find ways to improve the processes.

5.1.1 Comparison with Predicted Flows

- This feature allows you to see whether the processes are being performed as predicted.
- It compares the main parts of generated processes with the processes defined during design.

5.1.2 Detecting Exceptional Routes

- All Processes are displayed with overlapping when Process Filter is set to 100%
- Routes with low appearance frequency are disappeared accordingly when Process Filter is narrowed.
- Processes are automatically filtered by typical condition when executing the Typical Process Button.

- 35 -
Extract routes that include the specified transitions
- Details of process, which includes events with low appearance frequency, can be confirmed.
- Inadequate actions can be detected.

Extract routes that do not meet certain conditions
- Routes that do not meet some business governance conditions can be detected.

5.1.3 Detect Inefficient Processes
Detect repetitious processes

- Inefficient processes can be detected.

Routes can be ordered by descending repeats count.
Detect process loopbacks

- Processes that should optimize some business procedures can be detected.

Routes can be ordered by descending loopbacks count.
Detect processes that take a long time

- Processes that should improve some business procedures can be detected.

5.1.4 Displaying the Distribution of Action Time

Distribution of Action Time can be displayed as histogram.

If some properties are existed, property value is linked to each event. Using this, statistical information of action time can be displayed as well.

Action, which has the longest average action time, is emphasized with red color when checking the “Highlight Bottlenecks”
5.1.5 Display Property Distribution

If some properties are existed, property value is linked to each event. Using this, property distribution can be displayed as histogram.

5.1.6 Looking at Trends in Routes

- According to left diagram, almost processes are concentrated on one main route. It means that improvement of business may be achieved if main route is optimized.
According to right diagram, processes are diversified into various routes. It means that many patterns should be taken into consideration for improvement of business.

5.2 Fixed-point Analysis with Process Discovery

Detecting actions that do not comply, checking the results of improvement activities etc can be done by regular process generation using Analytics sensor.

5.2.1 Detecting Actions that do not Comply

---

<Process Analyzer> An alert is configured on this action as Exceptional Action

<Dashboard> Process Id is identified from Alert detail screen.

<Process Analyzer> Detail of target Process is searched.
5.2.2 Checking the Results of Improvement Activities

- Process Analyzer
  - A chart is configured on this action as monitoring point.

- Dashboard
  - A result which action time fell below the threshold can be confirm by KPI Chart on Dashboard.
